

```

import deepchem as dc

# 1. Define our dataset of molecules (just Aspirin for now)
smiles_data = ["CC(=O)OC1=CC=CC=C1C(=O)O"]

# 2. Initialize the translator (the Featurizer)
# We use MolGraphConvFeaturizer to turn the molecule into a Graph
featurizer = dc.feat.MolGraphConvFeaturizer()

# 3. Perform the translation
graph_data = featurizer.featurize(smiles_data)

# Extract the graph object for our single molecule
aspirin_graph = graph_data[0]

# 4. Let's inspect the mathematical structure DeepChem built
print(f"Number of atoms (nodes): {aspirin_graph.num_nodes}")
print(f"Number of node features: {aspirin_graph.num_node_features}")

```
